

IRC command

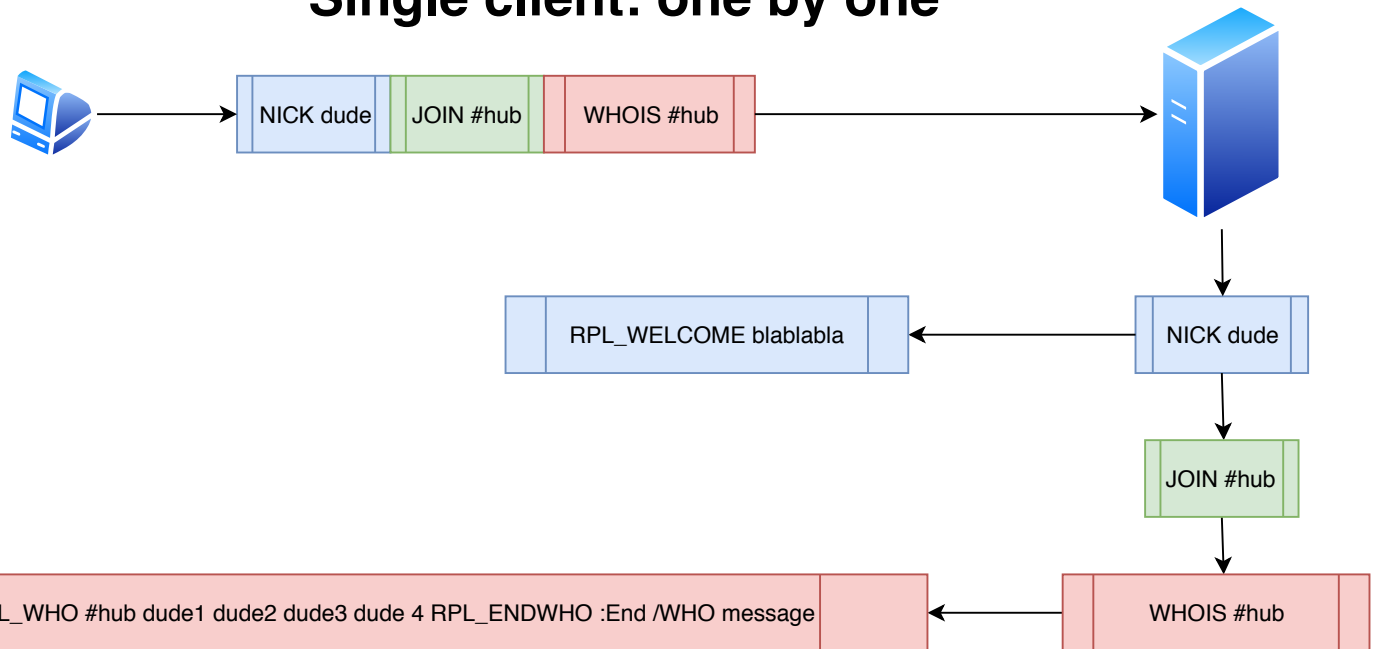

client

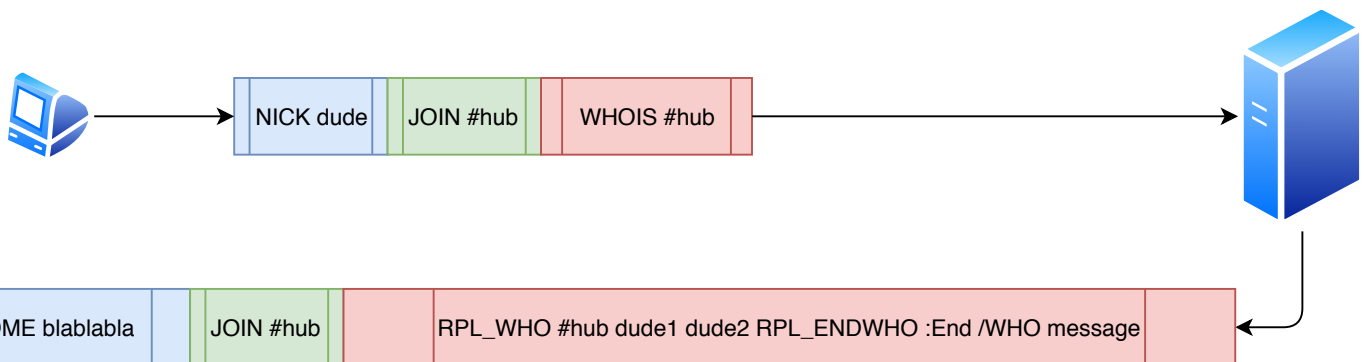

server

## Single client: one by one

## Single client example: all in one

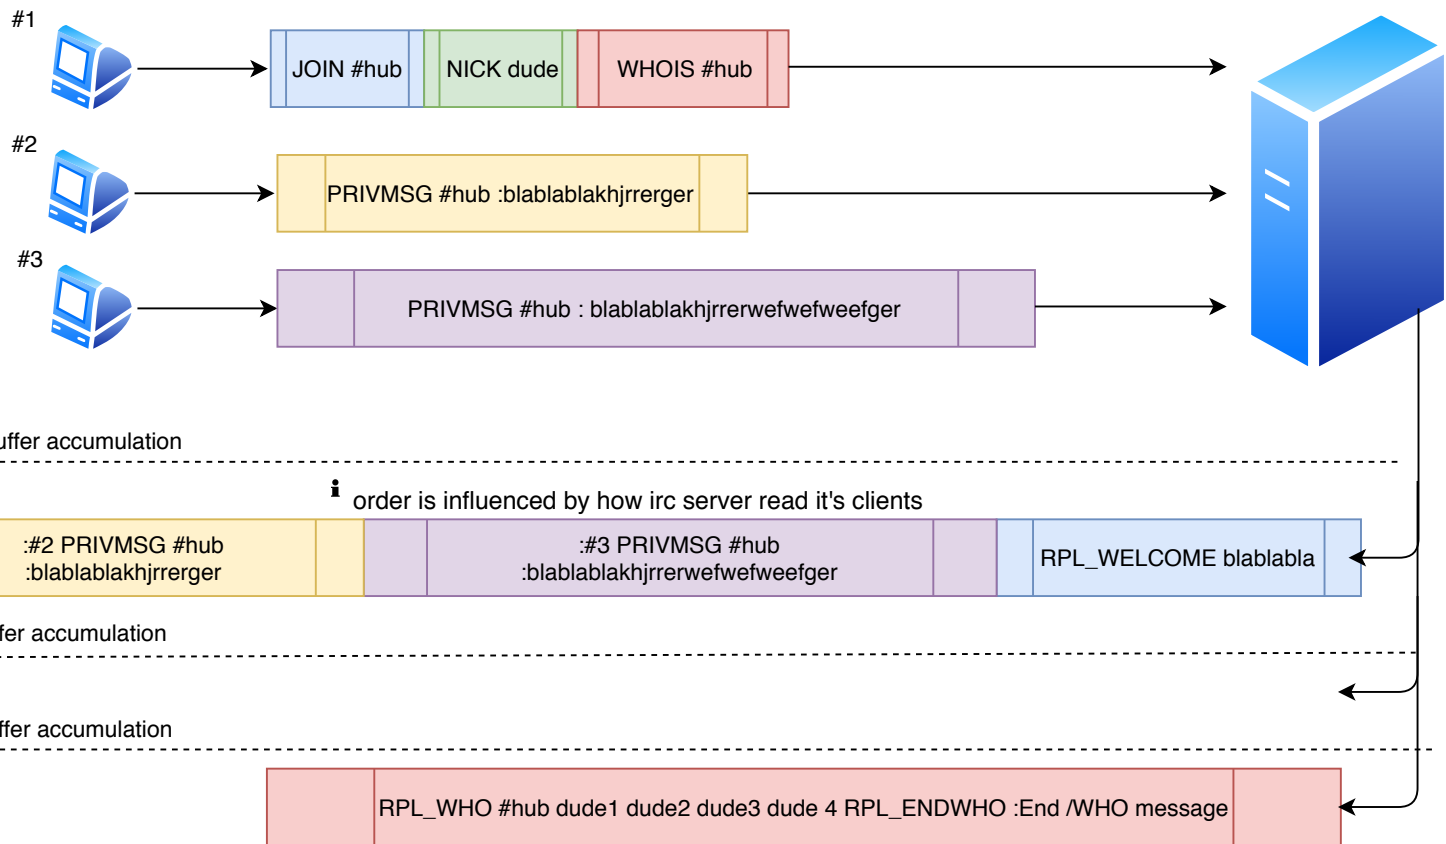

The risk packing responses may be to fill the output buffer too fast.

Handling messages one by one reduce output buffer full risk and reduce data loss.

On the other side, input command spend more time into irc buffer/socket cache.

But, the difference between input and output buffer is that output buffer is filled by other clients commands too.

# Multi clients example: one by one

# Multi clients example: all in one
